

How "Big Data" impacted Atmospheric Sciences?

Pedro Leite da Silva Dias
Institute of Astronomy, Geophysics and Atmospheric Sciences
University of São Paulo

Premises

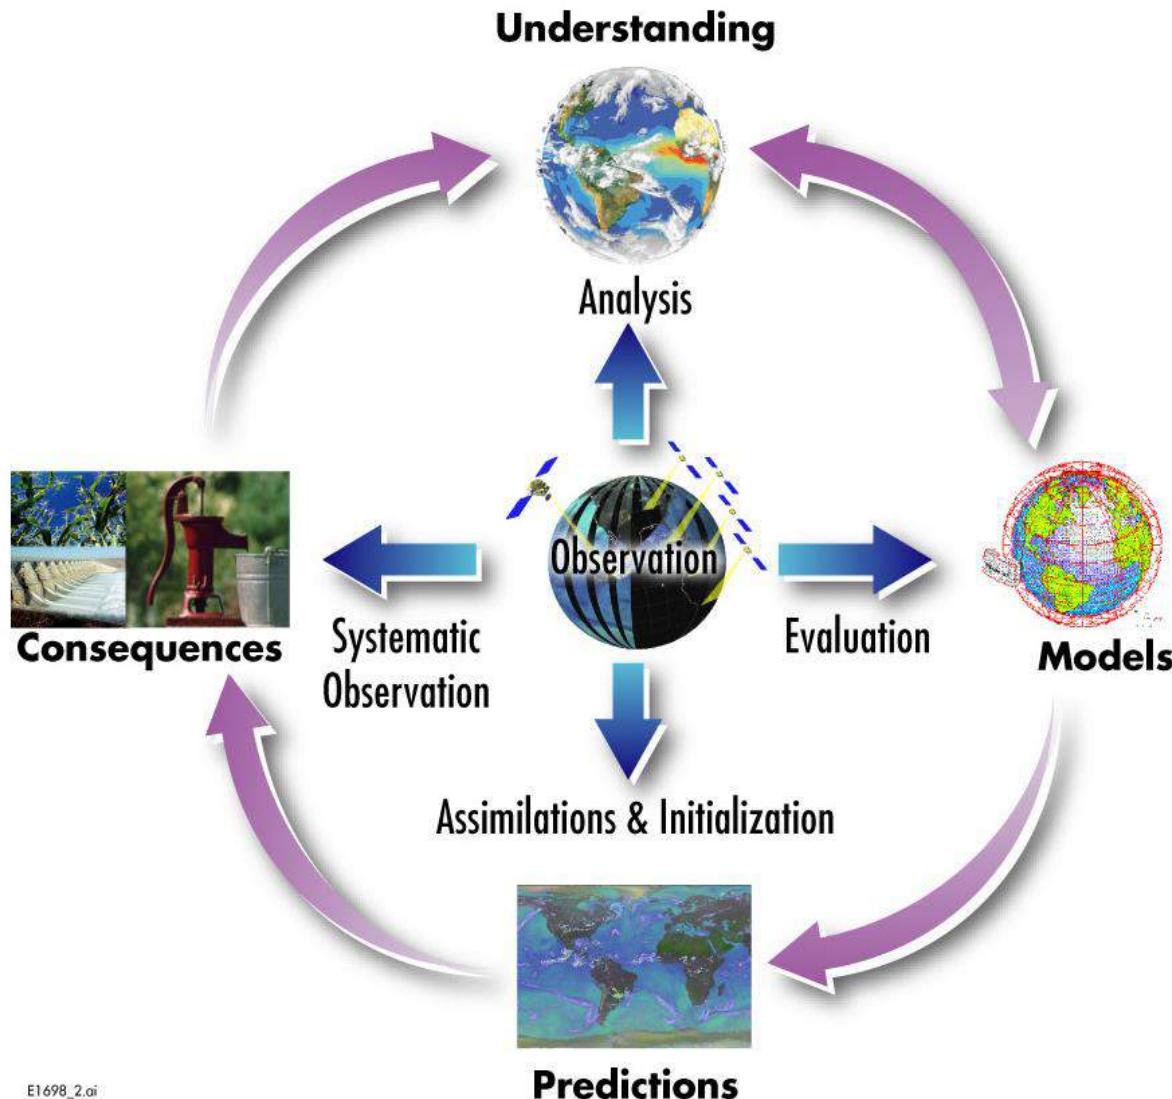

- Large impacts of knowledge-discovery through Data Mining in health informatics, marketing, business intelligence, and smart city, where big data science contributed to several of the most recent breakthroughs.
- However, in Weather and Climate Prediction to date, this potential has not been fully realized, in spite of the exponential growth of climate data.
- Success in nowcasting – short time (e.g based on Deep Neural Network – DNN) and huge amount of data from remote sensing (radar + satellite + surface based data)
- This disparity stems from the complexity and variety of climate data, as well as the scientific questions climate science brings forth.

Future

- Some challenging problems; ensemble forecasting, data assimilation, theoretical studies on causality ...
- Required steps to improve training in Data Science Applications in Atmospheric Sciences

Examples on identification of climatic patterns with large socio-economical impacts:

- Climate Patterns - El Nino/La Nina (Southern Oscillation)
- Pacific Decadal Oscillation
- Atlantic Meridional Mode
- Indian Ocean Dipole
- PNA, PSA, EU, etc.....

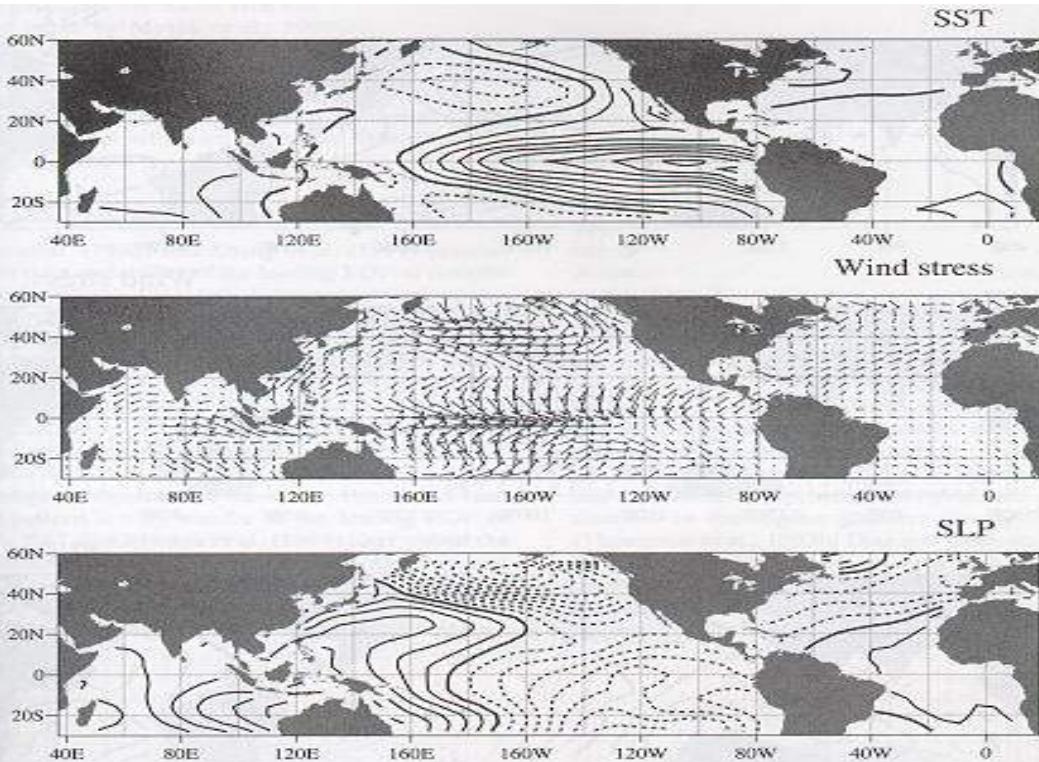

FIGURE 3-6 Global SST pattern, wind stress, and sea-level pressure that is related to the interannual variability associated with ENSO, based on linear regression between a high-pass-filtered "cold-tongue index" (CT) and global SST. (From Zhang et al., 1997; reprinted with permission of the American Meteorological Society.)

Indicators of the Atlantic
Meridional Overturning
circulation

- Lots of papers on pattern identification of climatic modes: EOF's, SOM, DNN (space/time)
 - Also on possible role of solar cycles
- Causality studies - networking
- However, limited success in predicting temporal evolution Transitionsof climatic patterns and also weather patterns on time scale beyond a few days.

Why?

Modeling the Earth Atmosphere System

*Non-linearity of the weather/climate
prediction problem*

$$\frac{\partial \xi}{\partial t} + \Omega \xi = N \quad (1)$$

Eigenfunctions of the linear operator form an orthogonal and complete set

$$\xi(x, y, t) = \sum_a c_a(t) \xi_a(y) e^{ik_a x} \quad (2)$$

$c_a(t) \longrightarrow$ Spectral amplitudes

Conjugate modes $(a, a^*) \Rightarrow a = (k_a, \omega_a, n_a, r_a)$

$$a^* = (-k_a, -\omega_a, n_a, r_a)$$

Two conjugate modes are mathematically independent and physically equivalent $\Rightarrow c_{a^*}(t) = -c_a^*(t)$

Substituting (2) in (1) – vector form of the model, multiplication by the conjugate of the eigenfunctions $\xi_a(y)$ and global integration lead to:

$$\frac{dc_a(t)}{dt} = i\omega_a c_a(t) + \sum_b \sum_c \sigma_a^{bc} c_b^*(t) c_c^*(t) \quad (3)$$

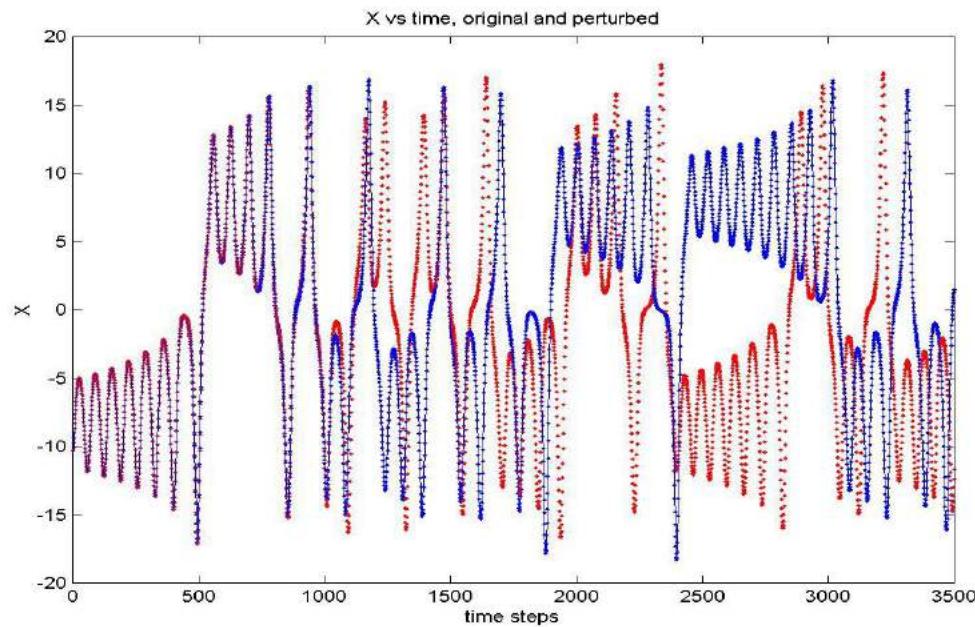

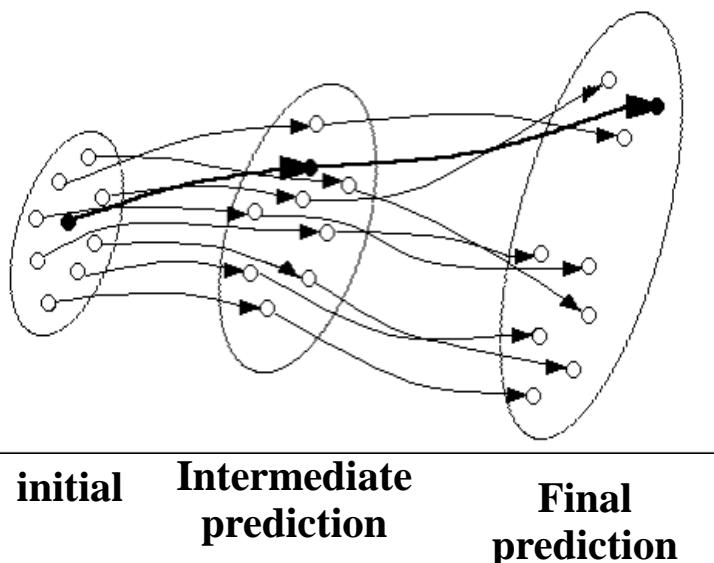

$$\sigma_a^{bc} = -\delta_{abc} \left\langle \left\{ u_b ik_c \xi_c + v_b \frac{d\xi_c}{dy} + [0, 0, 1]^T \phi_b \left(ik_c u_c + \frac{dv_c}{dy} \right) + CP \right\} \bullet \xi_a^* \right\rangle$$

Coupling coefficient among the modes a, b and c. These coefficients are real and invariant under permutations of the superscripts bc.

Typical Dimension in Operational Models: $10^{10} - 11$

Lorenz (1963, 1965, 1969):

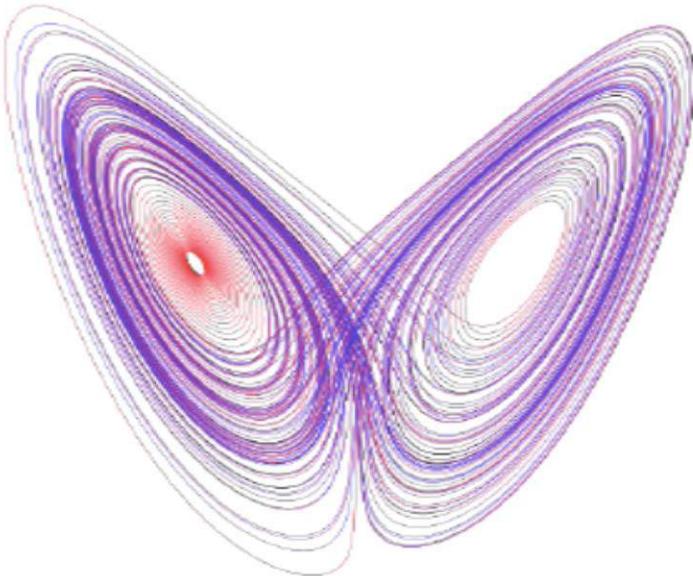

- Governing equations show strong dependency on the initial conditions;
- Slightly different initial conditions lead to significant changes in the forecast after a few days;
- Lorenz hypothesizes that 10 days would be the predictability limit...

How can we predict weather beyond 10 days? - effect of slow forcing in Lorenz's model

'Predictability in the midst of chaos'

If we can't predict the weather beyond the next week or so, why is it possible to make seasonal forecasts?

What is the impact of boundary forcing, f , on Lorenz Attractor?

$$\begin{aligned}\dot{X} &= -\sigma X + \sigma Y + f \\ \dot{Y} &= -XZ + rX - Y + f \\ \dot{Z} &= XY - bZ\end{aligned}$$

Birth of Seasonal Forecasting
'Predictability of Monsoons'
J. G. Charney and J. Shukla, 1981

Nonlinearity => energy transfer among scales

Dynamics of resonant interaction

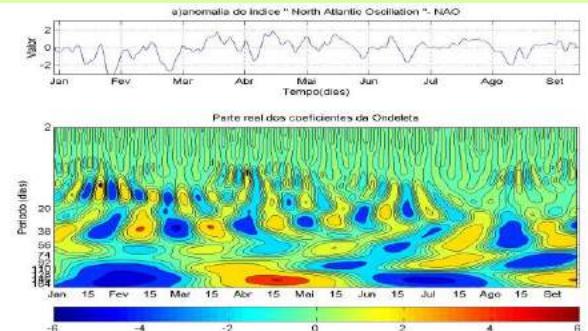

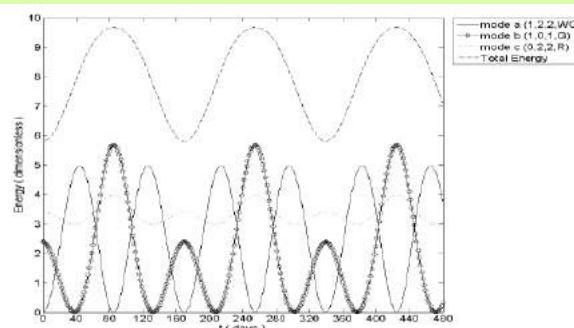

- Examples:

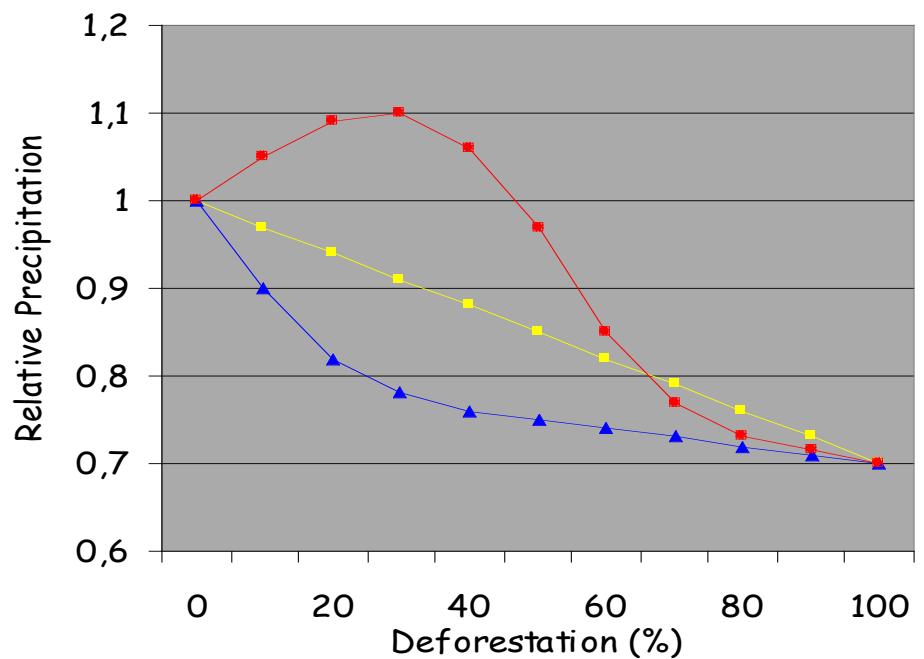

- Interaction between slow ($O(5\text{-}7\text{days})$) and fast modes ($O(1\text{ day or less})$) => intraseasonal scales (20-60 days) Raupp et al. (2008)
- Importance of diurnal variation leading to energy in intraseasonal time scales (Raupp and Silva Dias, 2009)
- Coupled ocean/atmosphere simplified models: interaction between intraseasonal scale ($O(20\text{-}60d)$) with interannual (El Niño/La Niña) - $O(2\text{-}3\text{ yr})$ => decadal/multidecadal time scales (Enver et al. 2017)

$$c_a^2 \frac{dA_a}{d\tau} = A_b A_c \eta_a^{bc} + q_a \delta\left(\frac{\omega_a \pm \nu_j}{\varepsilon}\right)$$

$$c_b^2 \frac{dA_b}{d\tau} = A_a A_c^* \eta_b^{ac} + q_b \delta\left(\frac{\omega_b \pm \nu_i}{\varepsilon}\right)$$

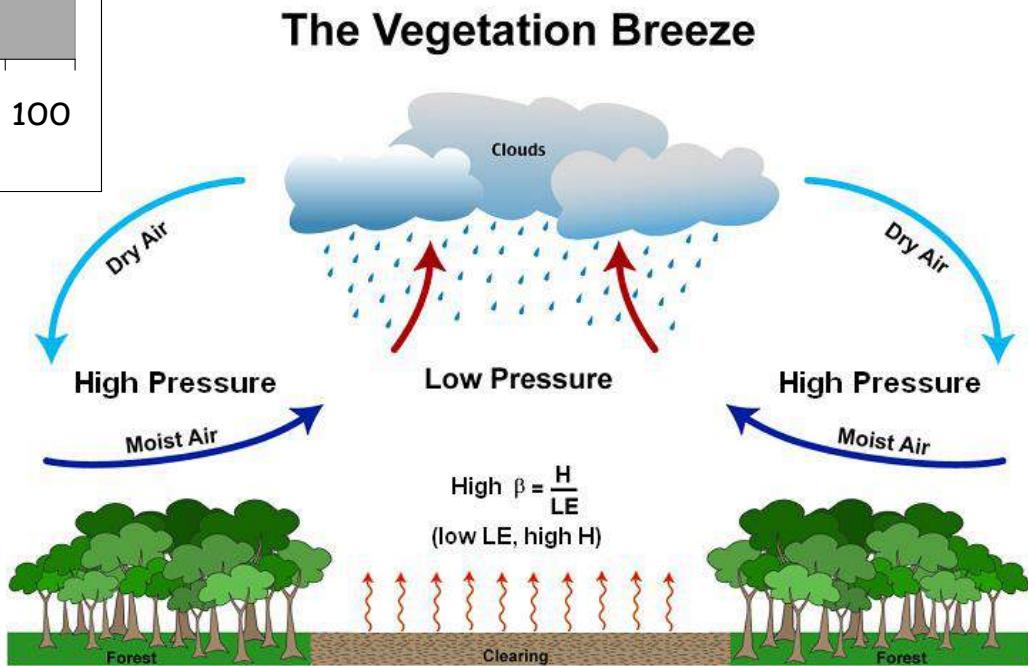

$$c_c^2 \frac{dA_c}{d\tau} = A_a A_b^* \eta_c^{ab} + q_c \delta\left(\frac{\omega_c \pm \nu_l}{\varepsilon}\right)$$

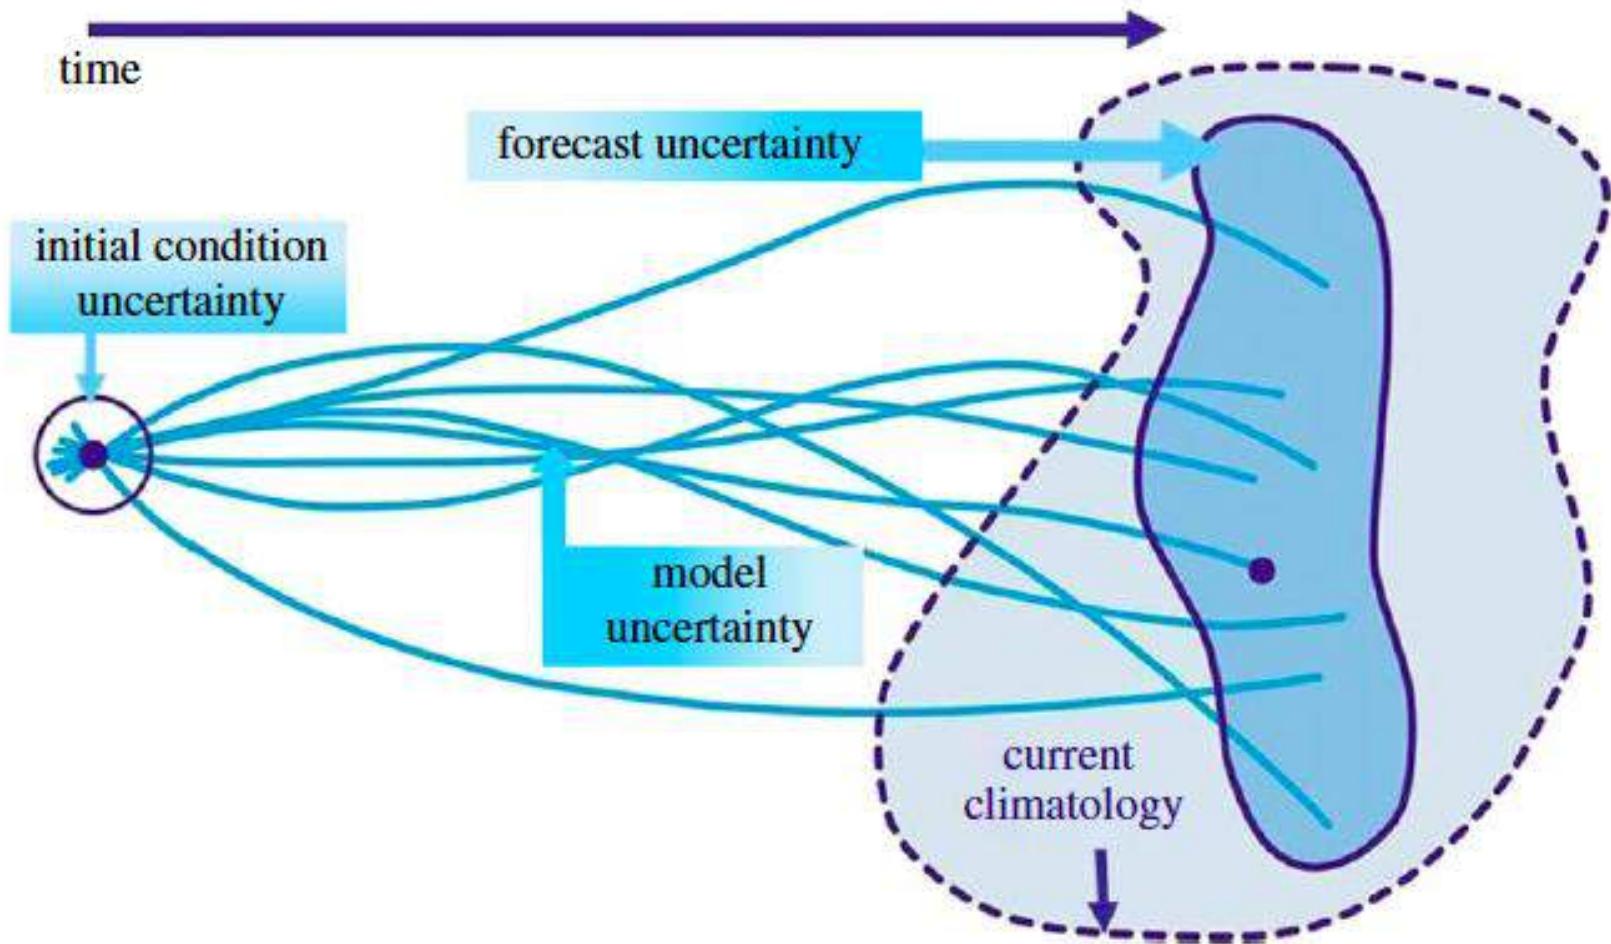

Precipitation change as a function of deforestation

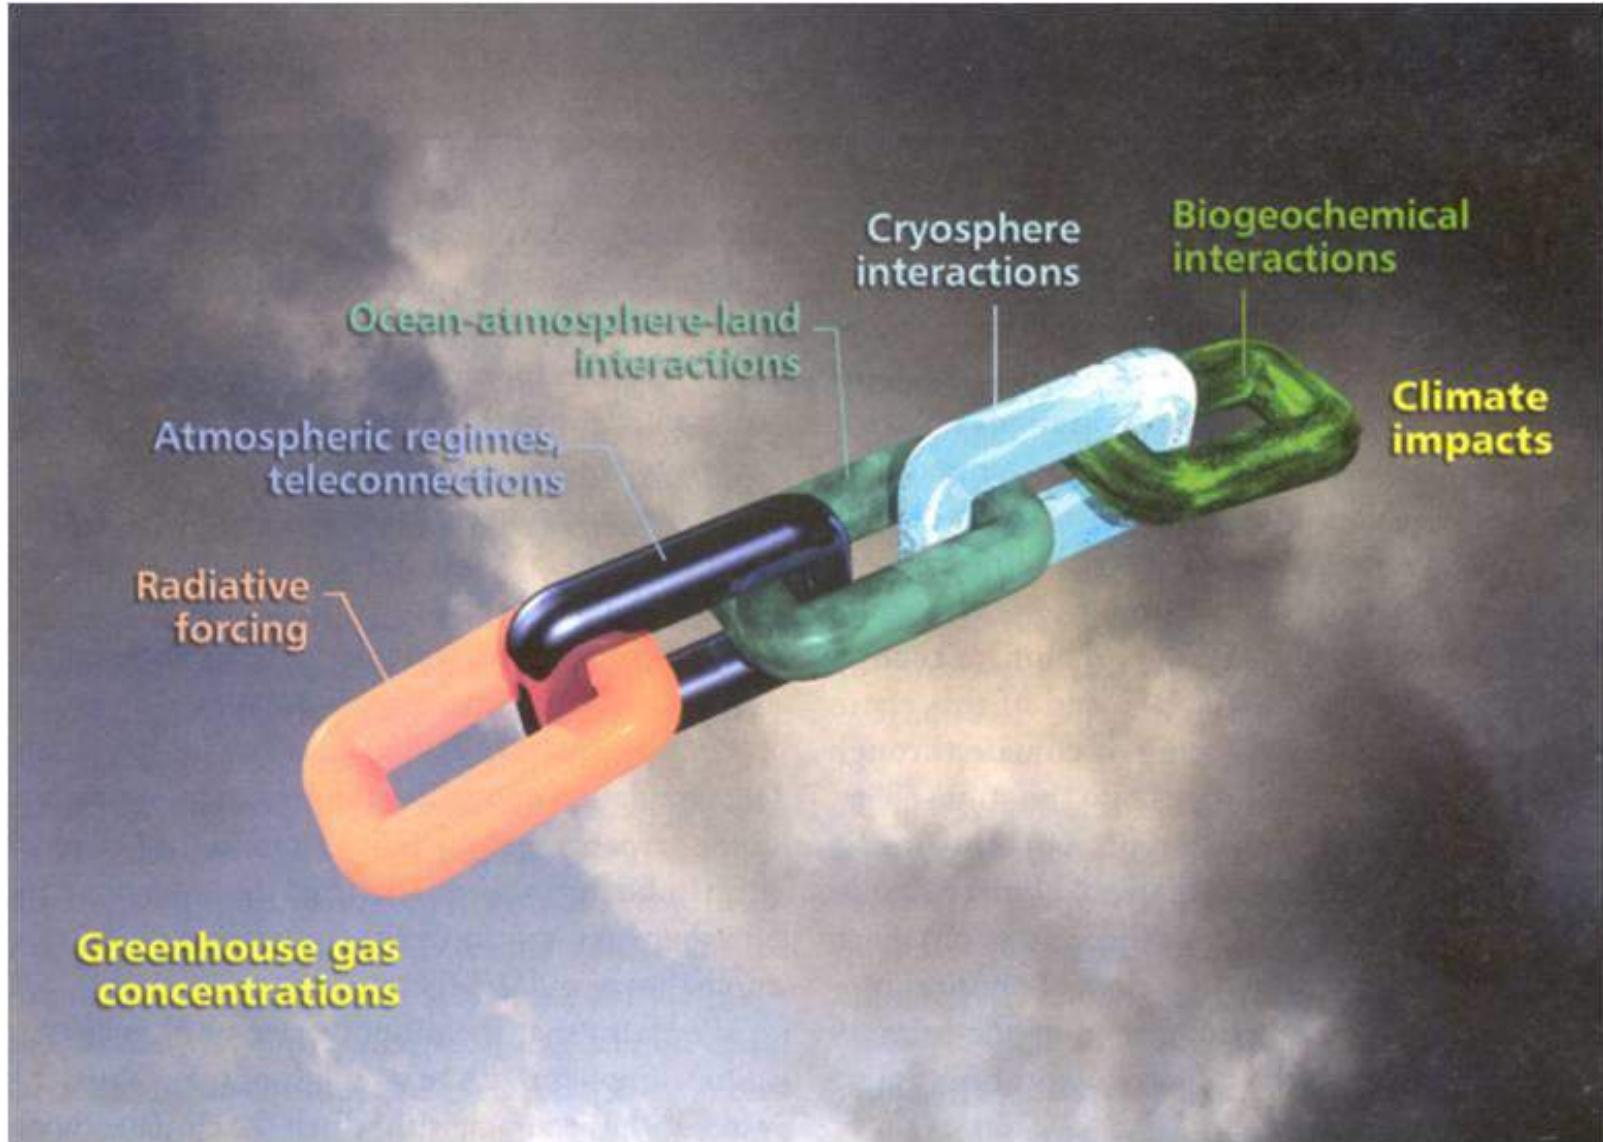

Conceptual impact of deforestation on relative precipitation. The three curves indicate different models, among many other possible ones (Avissar, P. Silva Dias, M. Silva Dias and Nobre et al 2002 – JGR – LBA special issue)

Message: realist deforestation patterns may lead to precipitation increase. Total substitution by pasture leads to drying. Need further studies on the impact of palm trees and other biofuel crops.

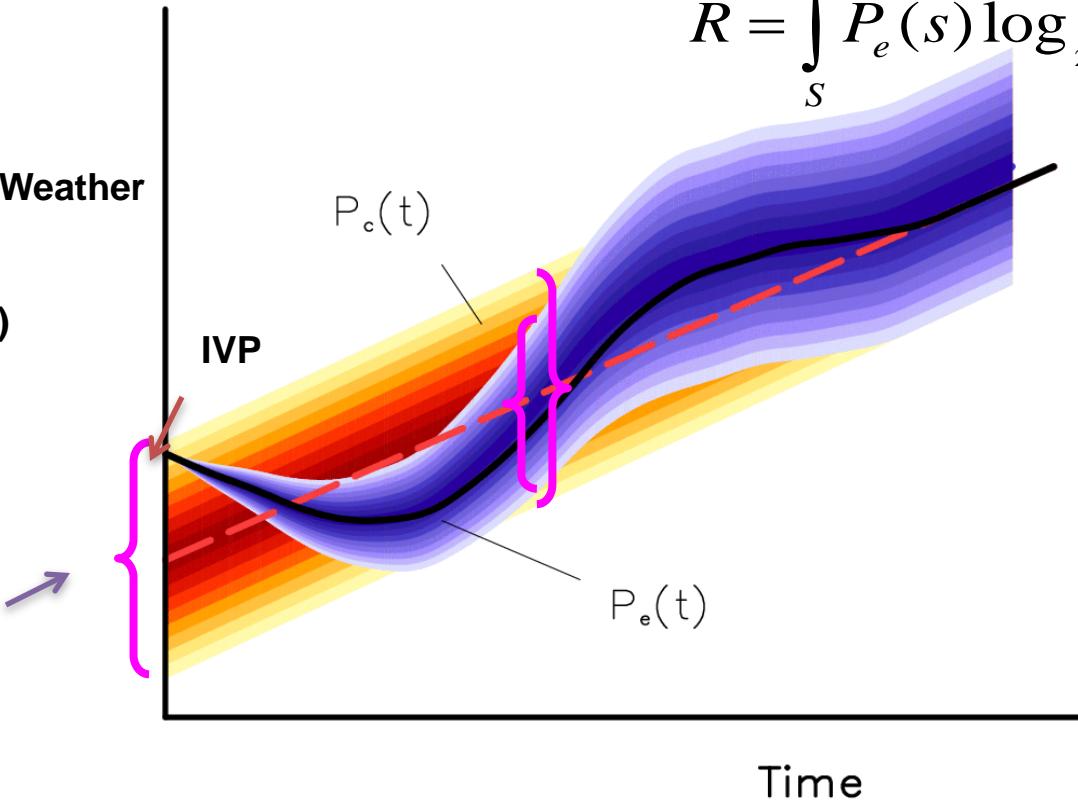

Climate is a complex system: interaction among several components

A HARD PROBLEM

Schematic Prediction (absent climate drift):

Initial value, Climate change & Total Predictability

$$R = \int_S P_e(s) \log_2 \left[\frac{P_e(s)}{P_C(s)} \right] ds \frac{1}{n}$$

Background or model forecast
Observation vector
Observation operator

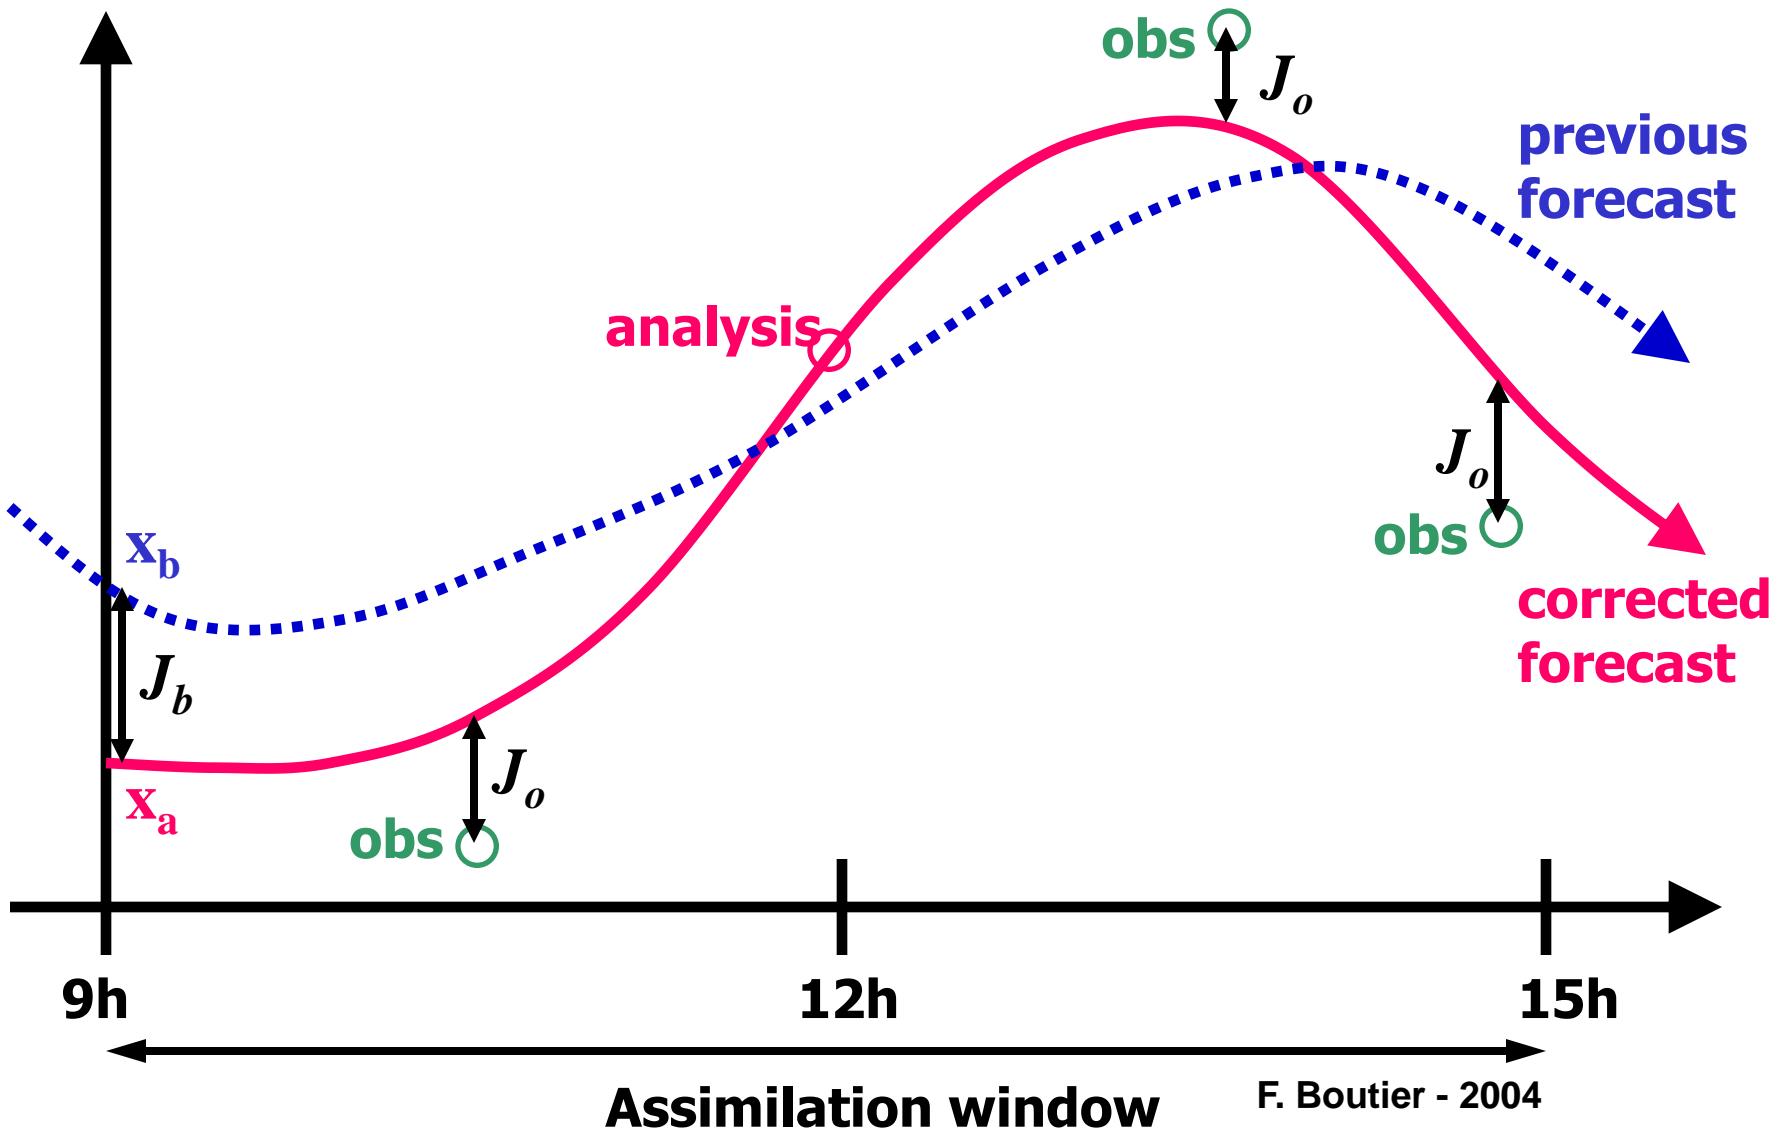

$$\mathbf{K} = \mathbf{B}\mathbf{H}^T (\mathbf{H}\mathbf{B}\mathbf{H}^T + \mathbf{R})^{-1}$$

$N \approx 10^8$

$M \approx 10^6$

Can't invert!

Principle of 4D-VAR assimilation

3D-Var used in operational forecasting centers

$$J = \min \frac{1}{2} [(\mathbf{x}_b - \mathbf{x}_a)^T \mathbf{B}^{-1} (\mathbf{x}_b - \mathbf{x}_a) + (\mathbf{y}_o - H\mathbf{x}_a)^T \mathbf{R}^{-1} (\mathbf{y}_o - H\mathbf{x}_a)]$$

Distance to forecast Distance to observations

- \mathbf{x} is a model state vector, with 10^{8-11} d.o.f. \mathbf{x}_a minimizes J
- \mathbf{y}_o is the set of observations, with 10^{6-9} d.o.f.
- \mathbf{R} is the observational error covariance
- \mathbf{B} the forecast error covariance.
- In 3D-Var \mathbf{B} is assumed to be constant: it does not include “errors of the day”
- The methods that allow \mathbf{B} and \mathbf{A} to evolve are very expensive: 4D-Var and Kalman Filtering.

3D-Var

$$J = \min \frac{1}{2} [(\mathbf{x}^a - \mathbf{x}^b)^T \mathbf{B}^{-1} (\mathbf{x}^a - \mathbf{x}^b) + (H\mathbf{x}^a - \mathbf{y})^T \mathbf{R}^{-1} (H\mathbf{x}^a - \mathbf{y})]$$

Distance to forecast

Distance to observations

at the analysis time

4D-Var

$$J = \min \frac{1}{2} [(\mathbf{x}_0 - \mathbf{x}_0^b)^T \mathbf{B}^{-1} (\mathbf{x}_0 - \mathbf{x}_0^b) + \sum_{i=1}^s (H\mathbf{x}_i - \mathbf{y}_i)^T \mathbf{R}_i^{-1} (H\mathbf{x}_i - \mathbf{y}_i)]$$

Distance to background at the initial time

Distance to observations in a **time window interval t_0-t_1**

Control variable $\mathbf{x}(t_0)$

Analysis $\mathbf{x}(t_1) = M[\mathbf{x}(t_0)]$

Climate Change Data Alone is Projected to Grow to Nearly 350 Petabytes by 2030

Weather prediction has been a big data problem for a long time

- Weather satellite and radar data
- Global weather prediction models
- Regional weather prediction models
- Surface, upper air, and aircraft data

Petabytes per day

Crowdsourcing of Weather Data: The New Big Data Frontier

- Example: atmospheric pressure from smartphones
- Potentially a billion sensors in a few years
- A number of smartphone apps allow folks to report current weather conditions

IBM, Google,several consulting companies
are exploring the use of sensors not in the
official

Dealing with uncertainties -2

2. Forecast model $f(X,t)$ -> $DX/Dt = f(X,t)$

$f(X,t)$ is not perfectly known:

- *Formulation of physical processes (radiation, turbulence, phase change of water – vapour, liquid, ice);*
- *Spatial resolution of the models (100km, 10km, 1km): how do we deal with upscaling?*
- *Numerical Methods: discretization*
- *$F(X,t)$ is a multivariate function: physical interactions among components not completely understood – uncertainties in parameters.*

Uncertainty with respect to initial conditions:

- ***Ensemble forecasting: perturbation of initial conditions:***

Initial condition uncertainties: Ensemble forecasting/prediction

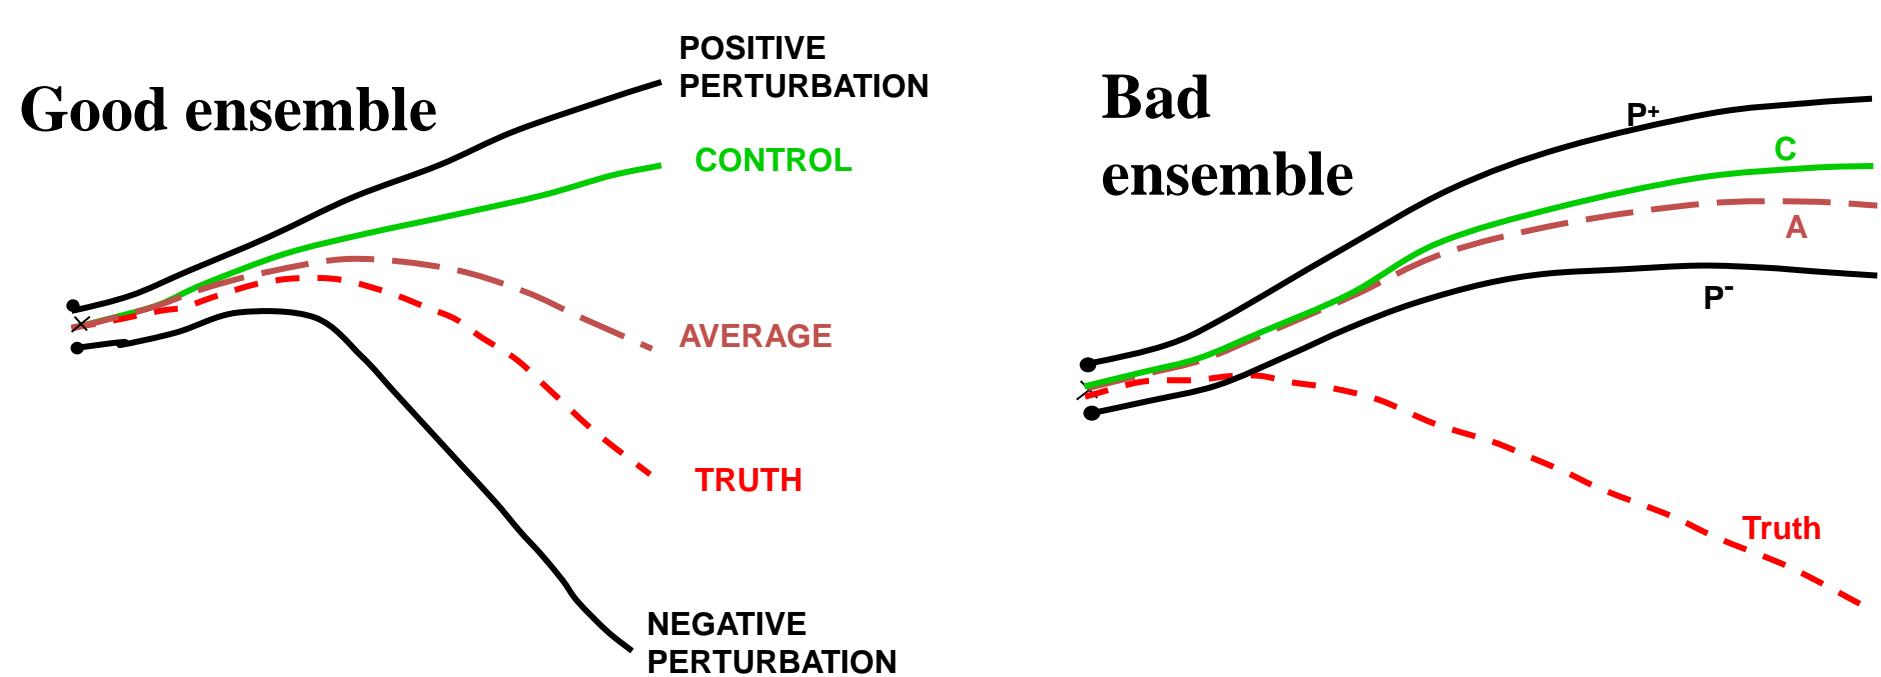

- Initial conditions not completely determined (X is a multivariate variable – large dimension - observations (Y) a few order of magnitudes smaller in dimension than X).
- One integration from a particular IC in general does not capture the complexity of the situation:
- Several integrations are needed, spanning the uncertainty in the model dynamics and initial conditions; perturbations/different models – merge with data assimilation uncertainties => **Ensemble Forecasting – huge amount of data!**
- Spread and differences between control and ensemble mean tell a lot about the system;
- **Need to be applied more generally in modelling the complex earth system (X_a, X_o, X_v, X_s, X_c , etc).**

Components of ensemble forecasts

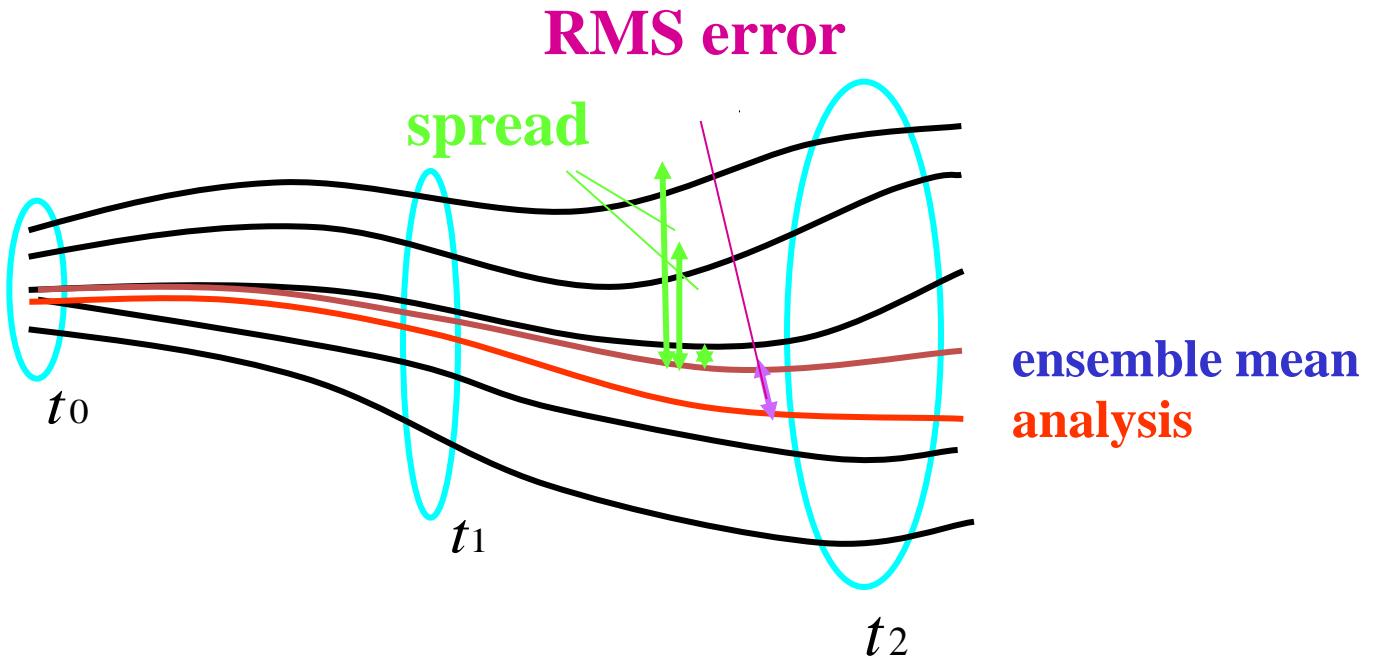

An ensemble forecast starts from initial perturbations to the analysis...

In a good ensemble “truth” looks like a member of the ensemble

The initial perturbations should reflect the analysis “errors of the day”

Representing initial state uncertainty by an ensemble of states

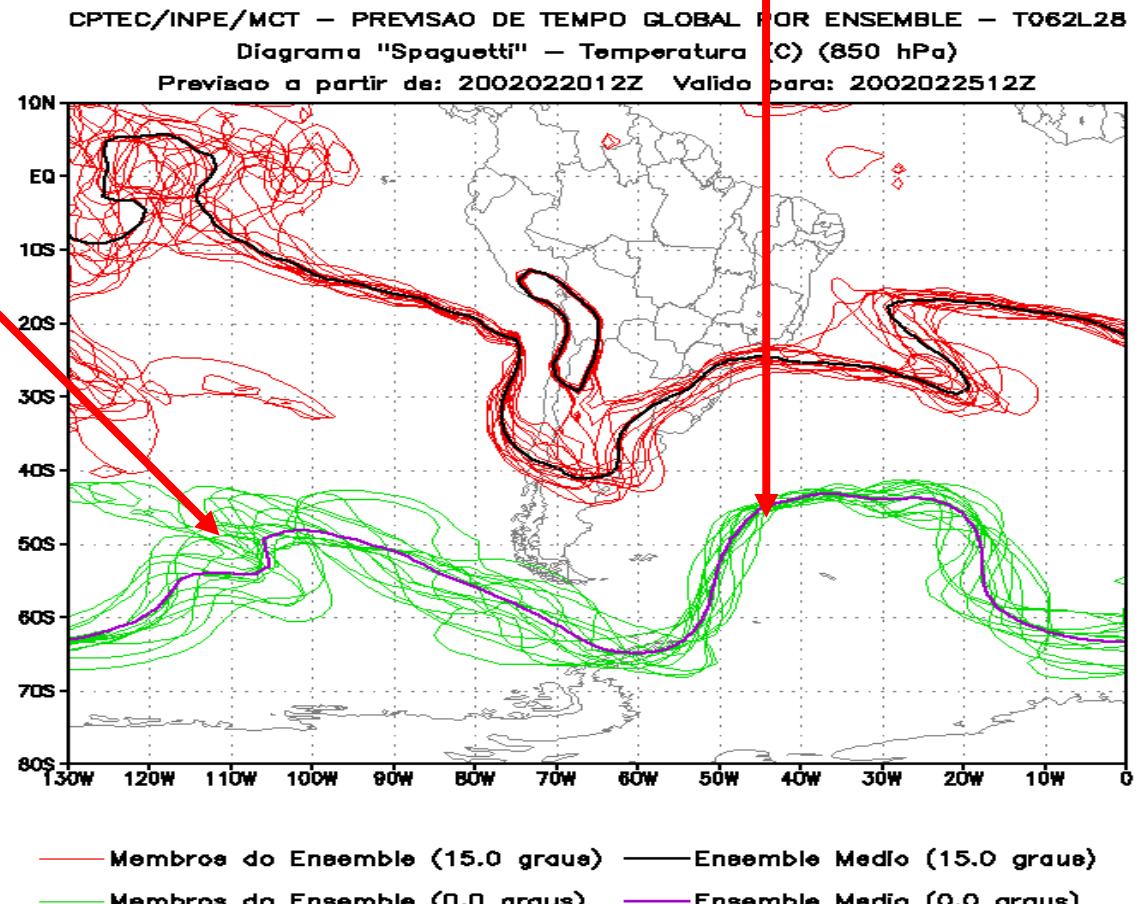

- Represent initial uncertainty by ensemble of atmospheric flow states
- Flow-dependence:
 - Predictable states should have small ensemble spread
 - Unpredictable states should have large ensemble spread
- ***Ensemble spread should grow like RMS error***

Example of ensemble prediction

Low predictability

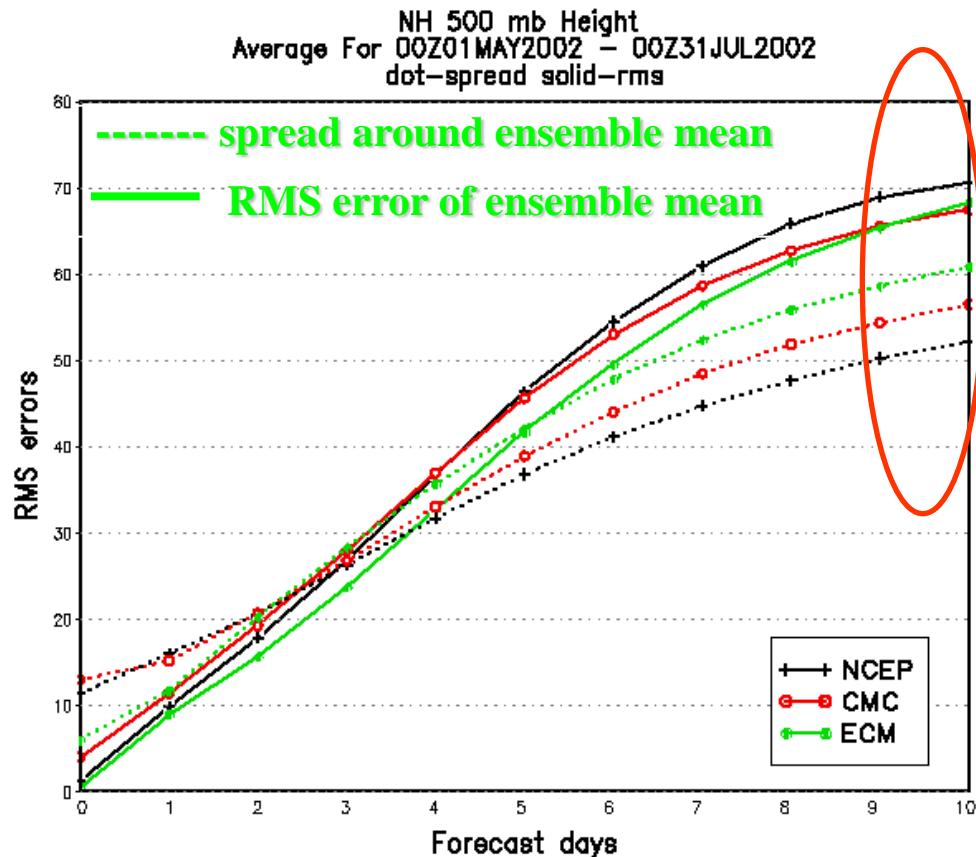

Operational product from Center for weather Prediction and Climate Studies - BRAZIL

Initial condition perturbation

Errors of the day tend to be localized
(Patil et al, 2001)

Under-dispersion of the ensemble system

The RMS error grows faster than the spread

- Ensemble is **under-dispersive**
- Ensemble forecast is over-confident

➤ Under-dispersion is a form of **model error**

➤ Forecast error = **initial error + model error**

Buizza et al., 2004

- A major restriction for accurate prediction is dynamical instability.
- Successful predictions in climate change science are hampered by the fact that the actual dynamics is a turbulent large-dimensional system with positive Lyapunov exponents on essentially all spatiotemporal scales;
- With unstable systems, the Monte Carlo (MC) sampling scheme may suffer from lack of robustness in the estimates it produces if employed with small samples and very costly if used with very large samples required to estimate probabilistic estimates.
- Several techniques for reducing sample sizes have been defined:
 - Bred vectors, singular vectors, influence function MC
...fertile area for data analysis!!!!

Roadmap for improving Ensemble Forecasting

Possible contributions:

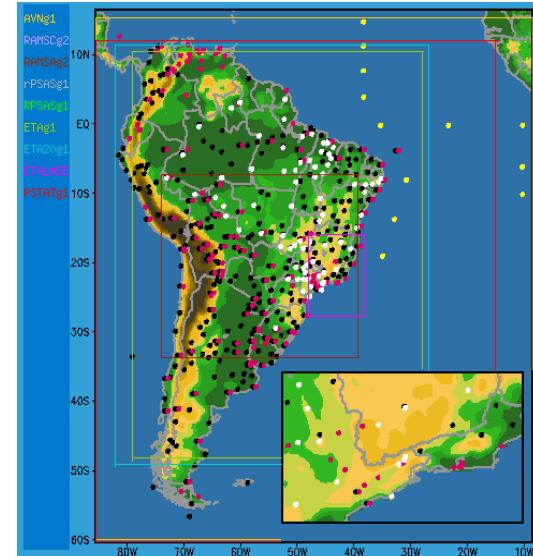

- Add more members – improving estimate of uncertainties associated with model: weather forecasting (association of major weather forecasting centers – TIGGE/WMO), climate forecasting (IRI, Eurobris...) and IPCC (climate scenarios for global warming); → (very high computational cost!!!)
- Application of Estimation Theory techniques for identifying optimal estimates (Bayesian techniques, ensemble Kalman filters and
- Genetic Programming, Neural Networks – deep learning techniques....);

An example on how to sample model uncertainties:

Model Intercomparison – Super Model Ensemble

Genetic programming

ABSTRACT

An evolutionary computation algorithm known as genetic programming (GP) has been explored as an alternative tool for improving the ensemble forecast of 24-h accumulated precipitation. Three GP versions and six ensembles' languages were applied to several real-world datasets over southern, southeastern and central Brazil during the rainy period from October to February of 2008–2013. According to the results, the GP algorithms performed better than two traditional statistical techniques, with errors 27–57% lower than simple ensemble mean and the MASTER super model ensemble system. In addition, the results revealed that GP algorithms outperformed the best individual forecasts, reaching an improvement of 34–42%. On the other hand, the GP algorithms had a similar performance with respect to each other and to the Bayesian model averaging, but the former are far more versatile techniques. Although the results for the six ensembles' languages are almost indistinguishable, our most complex linear language turned out to be the best overall proposal. Moreover, some meteorological attributes, including the weather patterns over Brazil, seem to play an important role in the prediction of daily rainfall amount.

Spatiotemporal Machine Learning Models for Precipitation Nowcasting

(a) For convolutional RNN, the recurrent connections are fixed over time.

(b) For trajectory RNN, the recurrent connections are dynamically determined.

Summary -1

- Data Assimilation techniques in the early 2000's had a remarkable impact!!! More than model improvements.
- 3DVar < 4DVar - Ensemble Kalman Filter competitive and numerically very efficient
- Insufficient ensemble model spread indicates the need to account for the statistical aspects of model error.
- Need to increase model independence (model diversity...)
- Super model ensemble based on simple Bayesian procedure : quite successful. Can be improved with AI – e.g. Genetic Programming Approach or Deep Neural Networks

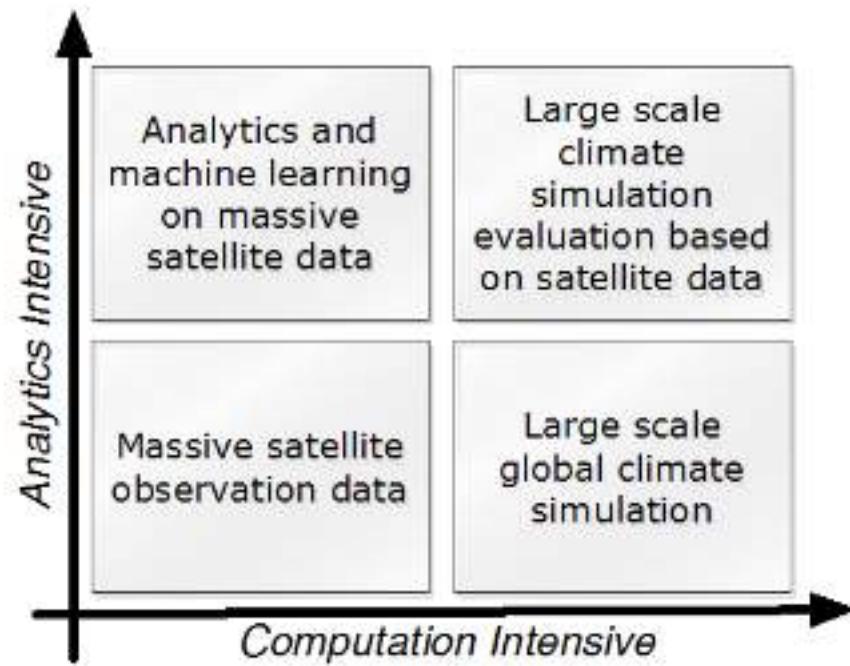

Fig. 1. Categorization of HPC and Big Data related challenges in cloud radiation and energy.

Training Challenges

- Lower cyberinfrastructure adoption on advanced data and computing techniques in the current atmospheric sciences curriculum;
- Lack of training research challenges in applicable domains for graduate students in Computing and Applied Mathematics in Atmospheric Science topics;
- Lack of customized training on the use of data science tools for students in Atmospheric Sciences.
- Lack of team-based multidisciplinary training and frontier research projects.

Summary -2

- **Training in Data Science for Atmospheric Sciences students:**
 - **How to prepare the next generation scientists?**
 - Data Science
 - High Performance Computing as an indispensable tool
 - Complex network analysis and climate science
 - Team work in challenging problems

“The whole problem with the world is that fools and fanatics are always so certain of themselves, and wiser people so full of doubts”

– Bertrand Russell

Modelagem Matemática

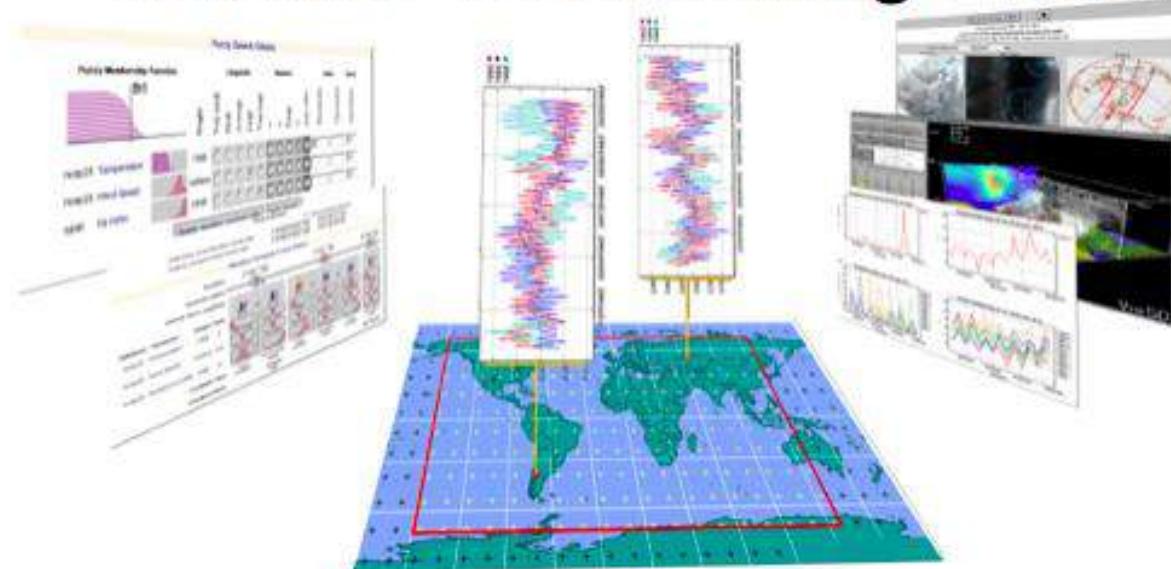

Construção de modelos matemáticos e técnicas de soluções numéricas utilizando computadores para analisar e resolver problemas científicos e de engenharia.

Challenge :

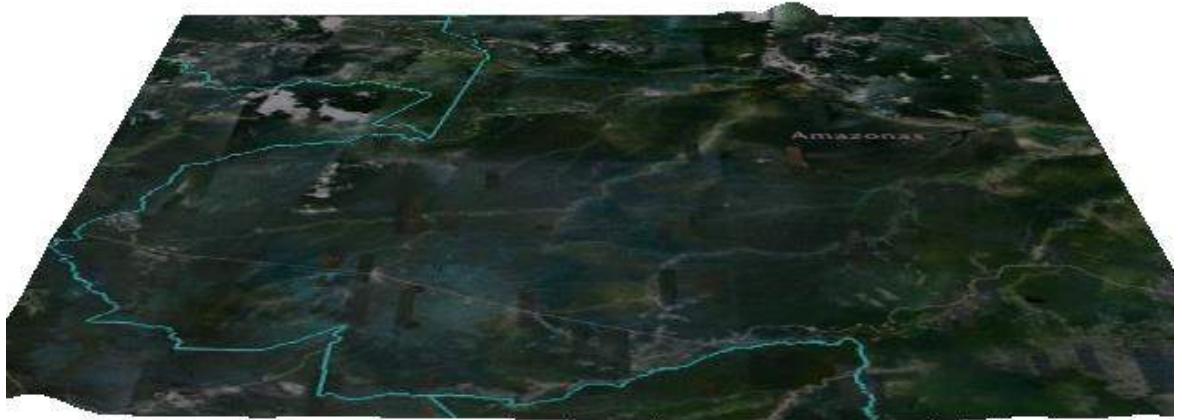

- ***Data Mining of massive data sets (3D animation, multiple fields)***

Meteorology and Space Weather Data Mining Portal

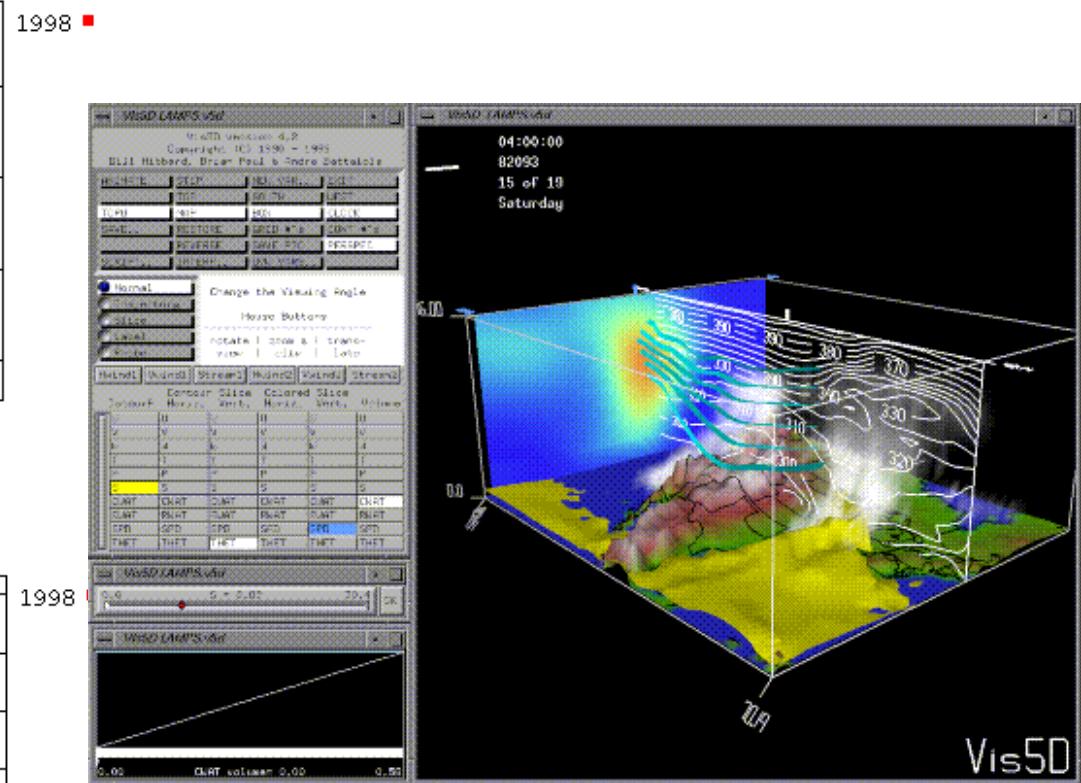

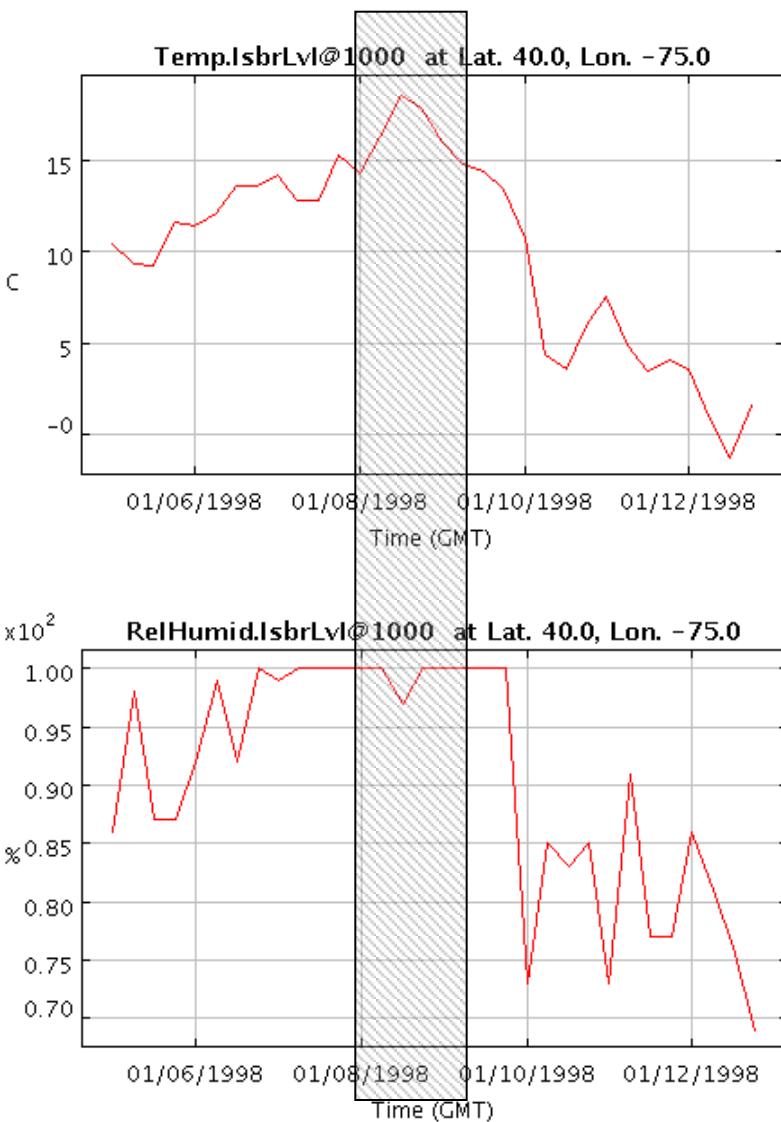

Mikhail ZHIZHIN, Geophysical Center RAS
Dmitry MISHIN, Institute of Physics of the Earth, RAS
Alexei POYDA, Moscow State University

- *Challenge :
Visualization
of massive
data sets
(3D
animation,
multiple
fields)*

Vis5D

Viewing the event in time and space

Vis5D time-space- parameter animation
